

Mixed*** (Ruminal Health or Fat in Ration)

NOTE
The elements presented here are simplified solutions. Since each farm is unique, it is strongly recommended to always consult a nutritionist and evaluate the economic impact of each change applied.

*** *This fatty acid group can be influenced by fatty acid supplementation*

Mixed fatty acids tend to follow either **de novo** or **Preformed**. The interpretation is therefore similar to these 2 other groups of fatty acids.

HIGH

- The rumen is healthy.
- Is your ration too safe*?
- Could your cows produce more*?

**If you are satisfied with the performance of your herd, do not change anything.*

Mixed are also very high when:

- The herd contains cows of several breeds (especially Jersey).
- Palm oil derivatives are added to the ration.

LOW below benchmark

- Does the rumen function well*?
- Validate the hypotheses of **de novo** below average (see card).

** If you are satisfied with the performance of your herd, do not change anything.*

LEGEND
Dark Curve – Your herd
Light curve – The average
