

Preformed*** (Ration Fat and Mobilization)

NOTE

The elements presented here are simplified solutions. Since each farm is unique, it is strongly recommended to always consult a nutritionist and evaluate the economic impact of each change applied.

*** *This fatty acid group can be influenced by fatty acid supplementation*

HIGH

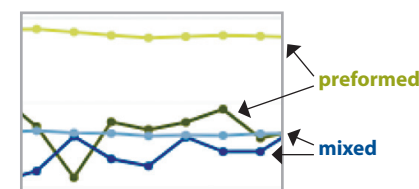

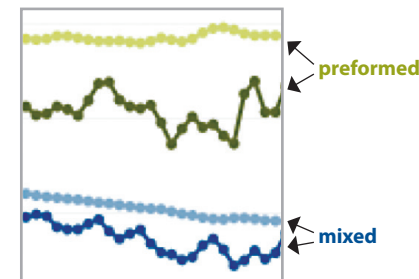

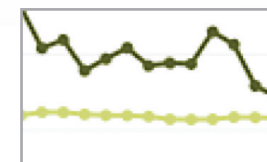

- Normal if the cows have just been put out to pasture or are consuming a large proportion of grass / grass silage.
- In any other situation: **CAUTION !!!!**
There may be an excess of fat in the ration (oils, beans, ...) or an important mobilization of body reserves.

SLIGHTLY LOW

- Often seen in herds with high corn silage rations.
 - Revalidate with **de novo** fats.
- * If you are satisfied with the performance of your herd, do not change anything.*

VERY LOW

- Close to the Mixed average.
- Cows appear to lack fatty acids in their diet.
- Validate the total intake and the type of feed provided to ensure enough essential fatty acids for the cow.
